# Operation of Rain Gauge and Groundwater Observation Well Networks for the Imperial Valley Water Authority Year Fifteen: September 2006-August 2007 

by<br>Nancy E. W estcott, K evin L. Rennels, and Steven D. Wilson

#### Abstract

The Illinois State W ater Survey (ISW S), under contract to the Imperial V alley W ater A uthority (IV W A ), has operated a network of rain gauges in M ason and T azewell Counties since A ugust 1992. The ISW S also established a network of groundwater observation wells in the M ason-Tazewell area in 1994, which is monitored by the IV W A. The purpose of the rain gauge network and the groundwater observation well network is to collect long-term data to determine the impact of groundwater withdrawals in dry periods and during the growing season, and the rate at which the aquifer recharges. This report presents data accumulated from both networks since their inception through A ugust 2007. Precipitation is recorded continuously at 20 rain gauges. Groundwater levels are measured at 13 observation wells. Ten of the observation wells are now outfitted with continuous digital recorders and three are hand measured periodically. The database from these networks consists of 15 years of precipitation data and 13 years of groundwater observations.

The Y ear Fifteen network precipitation of 31.94 inches was below average, 1.77 inches lower than the network 15-year average of 33.71, and 1.90 inches below the previous 14-year average of 33.84 inches. Overall, precipitation was near average, although the spring and summer seasons in $Y$ ear Fifteen were below average in seasonal total precipitation.

In 2006-2007, groundw ater levels continued to decline in some of the study area because of below average precipitation and increased irrigation demand. However, in much of the study area, water levels rebounded somewhat after the end of the 2006 irrigation season. The dry growing season of 2007 had an effect on irrigation water demands, with the amount of irrigation pumpage being the second highest total, second only to the 72 billion gallons pumped in 2005. Total irrigation for the J une-September 2007 period was estimated to be 57 billion gallons.

To improve our understanding of the relationship among groundwater, stream discharge, and irrigation pumpage, an irrigation test site was established in A pril 2003 (Y ear Eleven) near Easton, IL. Nine observation wells were installed in close proximity to an irrigated field that abuts Crane Creek. Transducers with data loggers have been installed in various wells since 2003 to monitor groundwater levels, and an additional logger was installed in Crane Creek to monitor stream stage. Data collection at the test site ended after the 2006 growing season. These data will be included in a groundwater flow model, currently in development. Data indicate there is groundwater discharge into Crane Creek at the test site even during irrigation withdrawals. The groundwater data indicate a rapid (within 24 hours) response of groundwater levels to precipitation, probably due to the increase in stage in Crane Creek in this area of prevalent sandy soils, though shallow water levels also are a contributing factor.

## Introduction

The Imperial V alley area, a portion of which also is called the Havana Lowlands, is located principally in $M$ ason and southern Tazewell Counties in west-central IIlinois, just east of the Illinois River (Figure 1). The area overlies the confluence of the ancient Mississippi and the M ahomet-Teays bedrock valleys. The sandy soils and rolling dunes of the confluence area in the western portion of the Imperial V alley stand in stark contrast to the typically flat silt loam soils throughout much of the rest of central Illinois. The sand-and-gravel deposits associated with these two valleys contain an abundant groundwater resource. The area is used primarily for row and specialty crops, and it is extensively irrigated from the easily developed groundwater resource that underlies the Imperial V alley.

Regional precipitation variability affects irrigation water demand on the aquifer, recharge to the aquifer, and the extent to which the aquifer can be used for agricultural irrigation and municipal, industrial, and domestic water supplies. All these factors affect any required water withdrawals from an aquifer. Therefore, knowledge of precipitation variability and its relationship to groundwater recharge over an extensively irrigated region, such as the area within the Imperial V alley W ater A uthority (IVWA ), should provide useful information for the management of groundwater resources in that region.

The Illinois State W ater Survey (ISWS) has a long-term interest in precipitation measurement and related research, and has performed precipitation research in areas such as hydrology, weather modification, climate change, and urban influences on precipitation climate. Scientists and engineers from the ISW S have conducted extensive research on Illinois groundwater resources and have a continued interest in the hydrodynamics and recharge of aquifers in the state.

The objective of this project is to conduct long-term monitoring of precipitation and groundwater levels in the Imperial V alley region to learn how groundwater resources respond to drought and seasonal irrigation, and to assess groundwater recharge.

## Rain Gauge and Observation Well Networks

A number of studies (W alker et al., 1965; Panno et al., 1994; Clark, 1994) have shown that precipitation is the primary source of water for groundwater recharge in the Imperial V alley. Therefore, detailed precipitation measurements are important for understanding its contribution to groundwater levels in the Imperial Valley area.

During the past 50 years, the ISW S has operated rain gauge networks of varying areal gauge densities over various time periods in both rural and urban areas. Sampling requirements, as determined from these past studies (e.g., Huff, 1970), indicate that a 2- to 3-mile gridded rain gauge spacing should be adequate for properly capturing convective precipitation systems (spring and summer), while a 6-mile spacing is adequate for more widespread precipitation-producing systems (fall and winter). The Belfort weighing bucket rain gauge provides precise and reliable precipitation measurements. Given the size of the IVW A area and the above spacing guidelines, a gridded, 25 -site rain gauge network (Figure 1) with approximately 5 miles between gauges was established in late A ugust 1992. The network was reduced to 20 sites in September 1996. Results of the previous years of the network operation are reported in Peppler and Hollinger (1994,

Figure 1. Configuration of the 13 -site observation well and 25 -site rain gauge networks, and location of the irrigation field site, Imperial Valley, 2006-2007
1995), Hollinger and Peppler (1996), Hollinger (1997), Hollinger and Scott (1998), Hollinger et al. (1999, 2000), Scott et al. (2001, 2002), W ehrmann et al. $(2004,2005)$, and Wilson et al. (2008a, b, c).

The observation well network originally consisted of 11 wells, M ason-Tazewell Observation W ells (M TOW) 1 through 11. The network was established for the IV WA in 1994 by Sanderson and Buck (1995). The IVWA added two wells (M TOW-12 and M TOW-13) in 1995 and 1996, respectively, to improve spatial coverage of the network. The 13 observation wells are located fairly uniformly across the Imperial Valley study area (Figure 1). Hollinger et al. (1999) includes the first summary of the groundwater-level data and statistical analyses of the correlation between precipitation, Illinois River stage, and groundwater levels for the four years that the observation well network had been in operation. Hollinger et al. (2000), Scott et al. (2001, 2002), Wehrmann et al. (2004, 2005), and Wilson et al. (2008a, b, c) include groundwater-level data and reanalysis of the correlation among precipitation, Illinois River stage, and groundwater levels for the observation well netw ork prior to Y ear Fifteen.

## Irrigation Test Site

Understanding the relationship between the regional groundwater discharge to streams and the effects of irrigation on water levels near these streams is a key component in developing a transient model of the Imperial V alley area. In order to model the conditions as they change during the summer, additional input data will be required on the effects of irrigation on groundwater levels and groundwater discharge to streams. Necessary data inputs for an ideal site include continuous water-level data, pumping rates and times for irrigation systems, and discharge/stage readings at a nearby stream, all at a location where groundwater is influenced by a stream and where the groundw ater system is under the influence of irrigation pumpage. A test site meeting these criteria was located along Crane Creek, near Easton, IL, in M ason County. The site has only one center-pivot irrigation system within a half mile of the creek, which provides some control over irrigation effects in the immediate vicinity. The site, owned by Jeff Smith, has been studied to gather some of the necessary data for input into a regional flow model and eventually a nested model of the site within the regional model.

## Report Objective

This report documents the operation, maintenance, data reduction and analysis, and management of the netw orks during the fifteenth year of the rain gauge netw ork operation and the thirteenth year of the observation well netw ork operation. A discussion of observed relationships among precipitation, Illinois River stage, irrigation, and groundwater levels is included.

Several appendices document groundwater hydrographs (A ppendix A), observed groundwater-level data (A ppendix B), rain gauge netw ork site descriptions (A ppendix C), instructions for rain gauge technicians (A ppendix D), and rain gauge maintenance for the 20062007 period (A ppendix E). The transducer data for the irrigation test site are included (A ppendix F). Contour maps of annual precipitation across the Imperial V alley are presented for Y ears One-Fourteen (A ppendix G). Documentation also is presented for the monthly and
seasonal 1992-2006 precipitation events (A ppendix H) and for all 2006-2007 precipitation events (A ppendix I).

## Acknowledgments

This work was conducted for the Imperial V alley W ater A uthority (IV W A ) with partial support from the Illinois State W ater Survey (ISWS) General Revenue Fund. The IV W A B oard under the direction of Mr . M orris B ell, chairman, administers the project. The views expressed in this report are those of the authors and do not necessarily reflect the views of the sponsor or the ISW S. Paul N elson and Robert Ranson run the rain gauge network, and M orris B ell collected the monthly groundwater-level data. Sara Olson drafted the precipitation maps for this report, Patti Hill assembled the report, and Lisa Sheppard edited the report. Their efforts are greatly appreciated. The ISWS and IVW A also take this opportunity to thank all of the local M ason/Tazewell County observers for their diligence in making this analysis possible. Special thanks are extended to J eff Smith of Easton, Illinois, for allowing the installation of nine observation wells at his farm and permitting our continual presence there to gather data.

## Rain Gauge Network: Description, Operation, and Maintenance

Peppler and Hollinger (1994) described construction of the IV W A rain gauge network and the type and setup of the weighing-bucket rain gauges used. Figure 1 shows locations for gauges R1-R25. A ppendix C gives complete site descriptions for the 20 operational rain gauges as of A ugust 31, 2007. A lso included are the locations of five rain gauges removed from the network in 1996. In December 1997, the rain gauges were upgraded to include a data logger and linear potentiometer to automatically record the amount of water in the rain gauges every 10 minutes. This eliminates the necessity to digitize weekly or monthly paper charts, saves two to three days of analysis time each month, and provides more accurate time frames for events. Precipitation also is recorded each month on eight-day paper charts for backup if data loggers fail.

The 20 active sites are maintained by a local $M$ ason County resident hired to change the charts once a month, download data from the data loggers, and perform other routine servicing. R ain gauge servicing includes checking the felt-tipped pen to make sure it is inking properly, emptying the bucket contents from approximately A pril-October, and noting any unusual problems, including chart-drive malfunction, gauge imbalance or instability, vandalism, unauthorized movement of the gauge, etc. During the warm season, evaporation shields are fitted into the collection orifice above the bucket to minimize evaporation. During the cold season, one quart of antifreeze is added to each rain gauge bucket so that any frozen precipitation collected will melt to allow a proper weight reading, and to prevent freeze damage to the collection bucket. R ain gauges are serviced during the first few days of the month. The memory card with the digital data and the 20 rain gauge charts are sent monthly to the ISW S. A ppendix D presents instructions for the rain gauge technician.

Champaign-based personnel visit the network to perform major maintenance and repairs as needed. This usually consists of a site assessment of an observer-noted problem and determination of a solution. Sometimes problems pertain to the chart drives, and the usual solution is to adjust or replace the chart drive. If replaced, the defective chart drive is cleaned and readied for reuse at the ISWS. Other typical repairs performed on these trips include resoldering wires and battery replacement. The 20 gauges are calibrated every two years. If a gauge appears to record consistently high or low precipitation amounts compared with its neighbors, the gauge is first cleaned and calibrated. If the problem persists, the gauge is replaced. A ppendix E documents non-routine maintenance or repairs, including any site relocations, for the 20 rain gauges during $Y$ ear Fifteen.

## Groundwater-Level Observation Well Network: Description, Operation, and Maintenance

Table 1 provides a general description of each network well, including well location, depth, and the predominant soil associations in proximity to each well. This provides some determination of relative soil permeability around the wells. Generally, the greater permeabilities associated with the Plainfield-Bloomfield, Sparta-Plainfield-A de, and Onarga-Dakota-Sparta soil associations (Calsyn, 1995) are found at M TOW $-1,-3,-4,-6,-7,-9$, and -12 , which are all located in the western portion of the study area (Figure 1). Fine-grained materials found in the upper portion of the geologic profiles at M TOW-10 and M TOW-11 (southeastern portion of the study area) indicate that the water levels in these two wells are under artesian conditions. Because water in these wells is under pressure, water-level responses may be different from those of other wells.

The observation wells range in depth from 24 to 100 feet. M ost network wells were constructed after 1985 as part of special studies within the Imperial V alley or for use in the observation well network. A few wells that existed prior to the development of the network were used for water supply. All of the network wells have been surveyed for well head elevation above mean sea level.

W ell M TOW-1, located at Snicarte, is an inactive, large-diameter, hand-dug domestic well that has been monitored by the ISW S since 1958. M TOW -1 has been incorporated into the Shallow Groundwater W ell Network of the ISW S W ater and A tmospheric Resources M onitoring (W A R M ) Program. This well is equipped with a Stevens Type F water-level recorder that produces a continuous record of the groundwater level on a 32-day paper chart. ISW S staff visit the well monthly to measure the groundwater level, change the recorder chart, and perform recorder maintenance. Therefore, a longer and more complete groundwater level record is available for this well than for any other well in the IV WA network.

Because the Snicarte well has been dry several times in recent years, a new well was drilled to replace it. The new well is located just south of the existing well, at the road intersection. This new well is currently named Snicarte \#2 to avoid any confusion with the original Snicarte well (M TOW-01), and will eventually take the place of the original well (M TOW-01 or Snicarte \#1) within the monitoring well network. The two wells must be observed for a period of time so that water-level data from Snicarte \#1 can be correlated to Snicarte \#2. The new well is equipped with the same type of Stevens recorder as the original well. It is unknown at this time how long this procedure will take as Snicarte \#1 has been intermittently dry.

From 1995 through 2001, groundwater levels in the IV W A observation wells were measured at the beginning of each month from $M$ arch through N ovember (December, J anuary, and February readings typically were not collected). Beginning in 2002, monthly measurements were collected throughout the entire year. A mid-month measurement was collected during the 19951997 irrigation seasons (M ay-O ctober 1995, M ay-September 1996, and M ay-A ugust 1997). Groundwater levels measured manually with a steel tape or electric probe are entered into a database as depth below land surface. The IV W A collected these measurements, maintained the database, and forw arded the resulting data annually to the ISWS.

In J anuary 2005, Y ear Thirteen, four of the wells (M TOW -2, -3, -7, -13) were outfitted with digital data loggers for collecting water level measurements. In Y ear F ourteen, six additional wells were outfitted with digital data loggers. Currently, the 10 observation wells with digital
records collect near-continuous measurements (every 6 or 12 hours). These data are downloaded six times a year, and water levels are sent to the IV W A for their use.

M TOW -5 and -9 are very near the Illinois River and previous measurements indicate their readings are a reflection of river stage, much more so than groundwater conditions. Because continuous river stage data are available, these three wells are no longer regularly measured.

## Irrigation Test Site: Description, Operation, and Maintenance (Year Five)

The irrigation test site along Crane Creek, southwest of Easton, IL, is located in Section 4 of Township 20 N orth, Range 7 West (Crane Creek Township) on property owned by M r. J eff Smith. Nine observation wells were installed in A pril 2003. Three are on the north side of Crane Creek and six are on the south side of Crane Creek. The irrigation well is on the south side of Crane Creek; its irrigation pattern, along with the observation well locations, are shown in Figure 2. The observation wells range from 31 to 37 feet deep, and the non-pumping water levels are less than 10 feet below land surface during the off-irrigation season. The depth and date of construction for each well are listed in Table 2. Data collection was completed during Y ear Fifteen at the site. M onitoring included groundwater level observations (manual and digital), surface water stage (manual and digital), discharge measurements, and measurement of well elevations.

Figure 2. Locations of observation wells and streamflow discharge measurement points in relation to the irrigation test site

A s of September 1, 2005, data loggers were installed in all wells at the site, and in Crane Creek near the downstream bridge. The data logger in well 1 was removed on A ugust 3, 2006, and the data logger in well 9 was removed on July 14, 2006. The remaining seven data loggers were removed on September 26, 2006. The data logger located within Crane Creek near the downstream bridge remains. The logger is serviced and a field check is done to verify accuracy a few times throughout the year.

D ata loggers placed at the site were set up to collect data at varying intervals. W ell 6 and the data logger in Crane Creek collected data at 15-minute intervals. Those in wells 4, 5, 8, and 9 were set to collect data every 30 minutes. In wells $1,2,3$, and 7 , the data loggers collected data every hour. Hydrographs of the transducer data for the site wells are provided in A ppendix $F$.

The measuring point elevations of the wells and stage readings were determined previously based on the downstream bridge elevation of 494.00 feet mean sea level (MSL) (taken from the U.S. Geological Survey topographic map). Elevations were surveyed from the downstream bridge so that relative water levels could be determined. The elevations are listed in Table 2.

Table 2. Depths, Installation Dates, and Measuring Point Elevations, Imperial Valley Irrigation Site Observation Wells

| Well number | Depth (feet) | Date installed | MP Elevation <br> $(M S L)$ |

## Precipitation, Groundwater-Level, and Irrigation Data Analysis

This report presents rainfall and groundw ater-level data for the period September 2006A ugust 2007, called $Y$ ear Fifteen in this report. Data collected from the rain gauge and observation well networks were maintained in separate databases, but the resulting data were evaluated together to examine the response of groundw ater levels to local precipitation. Observed network groundwater levels may be influenced by irrigation pumpage, so an estimate of monthly pumpage also is presented.

## Precipitation Analysis

D ata reduction activities during $Y$ ear Fifteen of network operation are similar to those performed during the previous 14 years (Peppler and Hollinger, 1994, 1995; Hollinger and Peppler, 1996; Hollinger, 1997; H ollinger and Scott, 1998; Hollinger et al., 1999, 2000; Scott et al., 2001, 2002; W ehrmann et al., 2004, 2005; and Wilson et al., 2008a, b, c). Hourly rainfall amounts are total ed from 10-minute digital data and are placed in an array of monthly values for the 20 gauges. This data array is used to check for spatial and temporal consistency among gauges, and to divide the data into storm periods. If the digital data are missing, hourly rainfall amounts from the analog (paper) charts are used. In the rare event that data from both a data logger and the corresponding chart are missing, the hourly amounts are estimated based on an interpolation of values from the nearest surrounding gauges.

## Groundwater-Level Analysis

## Monthly Measurements

Groundwater levels for each well for the period of record (1995-2007) are presented graphically (A ppendix A ) and in tabular form (A ppendix B). Graphs of groundw ater levels are commonly called hydrographs. E ach hydrograph also contains the total monthly precipitation for the nearest rain gauge. For observation wells located between several rain gauges, an average of the surrounding rain gauge data is presented. Groundwater level data are presented as depth-towater from land surface. For observation wells located relatively near the Illinois River (M TOW-1, -5 , and -9 ), the stage of the river at the nearest U.S. A rmy Corps of Engineers (USACE) gauging station also is shown. M ean monthly stage data were downloaded for the Beardstown, Havana, and K ingston M ines stations from the USACE Internet site (http://water.mvr.usace.army.mil).

## Continuous Measurements

Selected historical daily groundwater-level data from recorder chart records for the Snicarte observation well (M TOW-1) were transferred to digital format and graphed with daily rainfall data from gauge 24. The results, shown in the $Y$ ear Eleven report, indicate that there is indeed a quick response to rainfall at M TOW -1 . In response to those findings, transducers were temporarily installed in the Green V alley (M TOW -8) and Rest A rea (M TOW -7) wells during Y ear Twelve, which showed marginal success at correlating rainfall to groundwater-level changes. In Year Thirteen, four digital water level recorders were purchased and installed in wells M TOW -2, $-3,-7$,
and -13. In Y ear Fourteen, six more transducers were purchased and installed in wells MTOW-4, $-6,-8,-10,-11$, and -12 . M TOW -1 is the Snicarte observation well that has a continuous paper recorder. M TOW -5 and -9 are very near the Illinois River and historical data indicate that they are heavily influenced by the stage of the river. For this reason, transducers at these three locations would provide limited benefit.

## Irrigation Water-Use Analysis

Since 1995, the IV WA has estimated irrigation pumpage from wells in the Imperial V alley based on electric power consumption, using the equation below:

$$
Q=1505 \times \mathrm{KWH} \times \mathrm{IRR} / \mathrm{MEC}
$$

where Q is the total estimated monthly irrigation pumpage (in gallons), K WH is the monthly electrical power consumption (in kilowatt hours) used by the irrigation accounts served by M enard Electric Cooperative, IRR is the total number of irrigation systems in the IV WA region, M EC is the number of M enard Electric Cooperative irrigation accounts, and 1505 is a power consumption conversion factor (in gallons/K W H). Irrigation systems in the region receive electric power from the M enard Electric Cooperative and two investor-owned utilities (A merenCIPS and A merenCILCO). M enard Electric Cooperative provides the IV WA with electric power consumption data for the irrigation services they serve during the growing season (J uneSeptember). N ot all the irrigation systems use electric power to pump water, and $M$ enard serves only some of these systems. The pumpage estimate assumed that application rates for the irrigation wells with electric pumps in M enard Electric Cooperative also are representative of other utilities and other energy sources. Past estimates were based on the assumption that 33 percent of the irrigation wells were in M enard Electric Cooperative in 1995-1997, and 40 percent in 1998-2001.

In summer 2002, a U.S. Geological Survey (USGS) study indicated the need for a new power consumption conversion factor. A $n$ updated conversion factor was determined by recording electrical consumption while closely measuring the pumping rate at 77 irrigation systems. The updated value, 1259 gallons/K W H, is appreciably lower than the previously used factor of 1505 gallons/KWH, suggesting that previous estimates of water withdrawals may have overestimated pumpage by approximately 20 percent (i.e., pumping system efficiency is estimated to be 20 percent less than previously thought). Therefore, irrigation withdraw als for the years 1997 to the present were recalculated using the new formula, replacing earlier published estimates. Collection of additional data related to the irrigation systems (such as system age and size) and the conversion factors associated with those systems may further enhance withdrawal estimates.

## Results

## Precipitation

## Annual and Monthly Precipitation

The $Y$ ear Fifteen dataset was used to produce the following analyses: 1) monthly and annual (September 2006-A ugust 2007) precipitation amounts for each site in the IV WA network (Table 3); 2) the average precipitation pattern for the 15 -year network operation (Figure 3); 3) the total precipitation pattern for $Y$ ear Fifteen (Figure 4); 4) a comparison of total precipitation, precipitation events, and precipitation per event (Table 4); and 5) the average precipitation for each month in $Y$ ear Fifteen (Figures 5-10). The annual precipitation patterns for $Y$ ears $O$ neFourteen also are presented (A ppendix G).

The $Y$ ear Fifteen netw ork precipitation of 31.94 inches was below average, 1.77 inches lower than the network 15 -year average of 33.71 , and 1.90 inches below the previous 14 -year average of 33.84 inches. It was the ninth driest year in the 15 years of network operation. The spring and summer seasons in $Y$ ear Fifteen were below average in seasonal total precipitation.

Figure 7. Precipitation (inches) for J anuary 2007 and February 2007

Figure 10. Precipitation (inches) for July 2007 and August 2007

Figure 3 presents the 15-year network average, excluding sites 16,19 , and 21 during the period 1997-2002, and Figure 4 presents the annual precipitation pattern for Y ear Fifteen. During Y ear Fifteen, annual gauge totals varied from 27.75 inches at site 16 to 38.16 inches at site number 2 (Figure 4). Eight-inch gradients in annual precipitation are not unusual during any given year, as long as they are not replicated at the same gauges year after year, and are somew hat supported by surrounding gauges.

M arch and J une 2007 (Figure 8a and 9b) were the wettest months of $Y$ ear Fifteen, reporting network averages of 4.66 inches and 4.50 inches, respectively, followed by November 2006 (Figure 6a) with 3.86 inches of precipitation. A ugust 2007 was the driest month of the year (Figure 10b, 1.30 inches) followed by February and M ay 2007 (Figure 7b, 1.74 inches; Figure 9a, 1.75 inches).

Individually, November 2006, December 2006, and M arch 2007 were more than 33 percent above average (see Table 4). M ay 2007, July 2007, and A ugust 2007 received less than 67 percent of their respective average monthly precipitation. The remaining six months, September and October 2006, and January, February, A pril, and June 2007 were within $\pm 0.33$ percent of the 14year average precipitation.

The spring and summer seasons of 2007 were the wettest seasons of the year, and the winter 2006-2007 was the driest season. The spring and summer seasons, however, received below average seasonal precipitation. The summer of 2007 was $75 \%$ of the 14 -year average summer precipitation. The annual precipitation total for 2006-2007 was the ninth driest of the 15 years of network operation. The network received 23.61 inches less precipitation than in the wettest year (1992-1993) and 6.24 inches more than in the driest year (1995-1996).

## Storm Events

The number of netw ork precipitation periods were determined for the 15 -year period. $M$ ean monthly, seasonal, and annual numbers of these precipitation events are presented for each year (A ppendix H), and for 2006-2007 (Table 4). The monthly, seasonal, and annual numbers of precipitation events averaged over the 1992-2006 period also are presented (Table 4). A netw ork storm period was defined as a precipitation event separated from preceding and succeeding events at all network stations by at least three hours. Data for the individual netw ork storm periods also are presented (A ppendix I, Tables I-2 and I-3).

During Y ear Fifteen, there were 100 precipitation events, few er than the 14-year average number of events. Fewer events than average occurred in all seasons of the year. M ost events occurred in the spring and summer, as is typical. The amount of precipitation per event was above average in the fall of 2006 and winter of 2006-2007, but near average in the spring and summer of 2007.

The plot of the network average monthly precipitation time series (Figure 11) shows the monthly variation of precipitation. It is not uncommon for precipitation in five to six months of the fall-winter seasons to fall below 2.75 inches. This occurred in the five years from 1995-1996 to 1999-2000 and in the three years from 2001-2002 to 2003-2004. It is not unusual for precipitation in one or two spring and summer months to fall below 2.75 inches in any given year. In the four summers of 1995, 1996, 1997, and 2000, precipitation in three or four months during the springsummer seasons fell below 2.75 inches. From February 2005 through February 2007, only one
month had precipitation greater than 4.0 inches. From February 2005 through A ugust 2007, there were only three months with precipitation over 4.0 inches.

A total of 1803 network storm periods occurred during the 15-year observation period: 148 in 1992-1993, 102 in 1993-1994, 129 in 1994-1995, 98 in 1995-1996, 121 in 1996-1997, 134 in 1997-1998, 144 in 1998-1999, 156 in 1999-2000, 148 in 2000-2001, 122 in 2001-2002, 80 in 2002-2003, 110 in 2003-2004, 98 in 2004-2005, 113 in 2005-2006, and 100 in 2006-2007, resulting in a 15 -year average of 120 storms per year.

A ppendix I documents each netw ork storm period for $Y$ ear Fifteen with the date and hour of the start time, duration, number of sites receiving precipitation, network average precipitation, storm average precipitation, maximum precipitation received, station (gauge) where the maximum occurred, and storm recurrence frequency of the maximum observed precipitation. The network average precipitation is the arithmetic mean of the precipitation received at all network stations, and the storm average is the arithmetic mean of the precipitation received at stations reporting precipitation during the storm period.

Figure 11. Network average monthly precipitation (inches), September 1992-A ugust 2007
The storm recurrence frequency is the statistical probability of the recurrence of a storm with the reported precipitation (e.g., a 10-year storm would be expected to occur on average only once every 10 years at a given station, or have a 10 percent chance of occurring in any given year). The recurrence frequencies computed here are based on the total storm duration for the area. See A ppendix I for further explanation. A Iso included in A ppendix I is a table indicating the
precipitation received at each of the 20 stations for each network storm period (Tablel-3) for $Y$ ear Fifteen. Sites that exceed the one-year or more recurrence frequency are indicated in bold type (Table I-3). Previous years of network storm periods can be found in Scott et al. (2002) and in Wehrmann et al. $(2004,2005)$.

In the first 14 years of network operation, 64 of the 1703 storm periods produced maximum precipitation at one or more stations with a recurrence frequency greater than one year: 50-year (1 storm), 10-year (3 storms), 5-year (8 storms), 2-year (34 storms), and greater than 1-year but less than 2-year (18 storms). The 50-year storm (storm 153) occurred on September 13, 1993 and the 10-year storms on M ay 16, 1995 (storm 323), M ay 8, 1996 (storm 432), and July 19, 1997 (storm 580). These four heaviest storms occurred during the warm season months (M aySeptember).

Ten storms had a recurrence interval exceeding the one-year or greater recurrence frequency in 1992-1993, five in 1993-1994, six in 1994-1995, one in 1995-1996, three in 19961997, four in 1997-1998, four in 1998-1999, five in 1999-2000, and four in 2000-2001, eight in 2001-2002, seven in 2002-2003, five in 2003-2004, one in 2004-2005, and two in 2005-2006.

In Y ear Fifteen, four of the 100 network storm periods exceeded the one-year or greater recurrence frequency. Y ear Fifteen had a below average number of network storm periods and a near average number of heavy rainfall periods. One event exceeded the 5-year or more recurrence frequency. Three of the four Y ear Fifteen storm events were 1-year events with one occurring in June, one in July, and one in A ugust. The 10-year event occurred on M arch 30, 2007 (storm 1754).

## Groundwater Levels

## Monthly Measurements

The long-term hydrograph at M TOW-1 (Snicarte) in Figure 12 provides a reference for comparison with the shorter records of the other netw ork wells. The ISW S has recorded water levels in this well since 1958. A nnual fluctuations from less than 1 foot to more than 6 feet have been observed. B ased on the data we have available, these annual fluctuations often appear to be superimposed on longer term trends, perhaps 10 years or more. For the 49-year record, both the record low and high have been observed within the past 15 years. A detailed look at water levels since 1990 is shown in Figure 13. During and shortly after the drought years of 1988 and 1989, the water level fell to 40.5 feet below land surface from September 1989 until A pril 1990, the only time in its 45-year history that the well went dry, until it did so again in 2006. During the 1993 flood, groundwater levels rose almost 10 feet and peaked at approximately 30 feet in September 1993. In the years since then, groundwater levels in M TOW-1 show an almost linear decline until 1998, when water levels rose dramatically, recovering to peak levels similar to those observed in 1994 and 1995.

Groundwater levels in observation wells M TOW -5 and M TOW -9, because of their proximity to the Illinois River, have been found to fluctuate largely in response to river stage. Since these two monitoring wells are so strongly influenced by the Illinois River, the wells are not outfitted with data loggers and in the future will be measured infrequently. The rest of the monitoring well sites do not have monthly measurements taken because the data loggers have eliminated this need. The sites are visited as data loggers need servicing or as a need for data grows due to irrigation pumpage.

Figure 12. Groundwater levels at the Snicarte well, M TOW -1, 1958-2007

Figure 13. Groundwater levels at the Snicarte well, M TOW -1, 1990-2007

Over the course of the past few years, the study area has received below average rainfall. These below average precipitation totals coupled with irrigation withdrawals have affected groundwater elevations in the study area. This trend began in M arch 2005 when rainfall amounts fell below average and has continued overall since that time. During $Y$ ear Thirteen, it was reported that groundw ater levels were at or near the lowest levels since the study began, and for $Y$ ear Fourteen, they had dropped below those levels. Y ear Fifteen does not seem to have offered any relief as groundw ater el evations were still below normal (see the graphs in A ppendix A).

## Continuous Measurements

An analysis of the continuous record from the Snicarte well (M TOW-1) in the Y ear Eleven Report (W ehrmann et al., 2005) indicated that recharge often occurs within one to three days of the rainfall event and typically lasts three to five days after the rainfall event has ended. In other words, recharge occurs on a scale of days, not months after a precipitation event; thus using monthly water-level data to develop correlations with rainfall may not be meaningful. In response to this finding, during Y ear Twelve of the study, transducers were placed in the Green V alley (M TOW -8) and Route 136 Rest A rea (M TOW -7) observation wells to begin collecting continuous water-level data. The data indicated that indeed recharge was evident two to three days after significant rainfall events at these wells.

Based on these results, the IV W A purchased 10 data loggers that were installed in wells betw een December 30, 2004 and A ugust 2005. The hydrographs for these 10 loggers can be seen in Figures 14-23. Reviewing the groundwater-level data confirms that monthly hand measurements are not adequate for determining recharge events.

For $Y$ ear Fifteen, the rainfall events were very evident as recharge at the Easton well (Figure 24). The rainfall event during late February/early M arch produced nearly 2 feet of recharge within approximately 14 days. Other recharge events were evident throughout this project year that produced similar results. However, recharge was not as pronounced during irrigation seasons that were drier and when water use was high. The M ay to A ugust rainfall events showed this trend. On Figure 24 the nearly 2 -inch rainfall event on July 17, 2007, caused less than 0.5 feet of recharge, while a similar rainfall event at the end of $M$ arch produced nearly 1.5 feet of water level change. How ever, the rainfall events of $M$ ay through A ugust show that recharge was not as pronounced during the irrigation season when conditions were drier and water use was high.

A long with Easton, the hydrographs showing continuous water levels and daily rain gauge data for M TOW-12 and M TOW-07 are provided in Figures 25 and 26. Although the hydrographs show ing the recharge following precipitation for the Hahn Farm and Rest A rea are not as dramatic as at Easton, the information they provide is just as vital.

We anticipate that as more data are collected, recharge events will be evident on the water level hydrographs. The relationship of depth to water and distance from a stream, and their effect on the amount of recharge, will be more identifiable and quantifiable.

## Irrigation Water Use

For $Y$ ear Fifteen, the low precipitation early in the summer of 2007 affected irrigation, but not as dramatically as in 2005. Irrigation in J une was the highest J une pumpage for the length of the study. Total irrigation pumpage in 2007 was approximately 57 billion gallons (bg), which is the second highest irrigation amount, second only to the 72 bg pumped in 2005.
$M$ onthly and seasonal estimates of irrigation withdrawals are shown in Table 5. These data were calculated for the Imperial V alley by previously described methods. Total annual irrigation withdrawals, from highest to lowest, are as follows: 2005, 2007, 1996, 2006; 2001 and 2002 (equal); 2003; 2004; 1999; 1997 and 1995 (equal); and 1998 and 2000 (equal). Typically, irrigation withdrawals are greatest in July and A ugust; September and J une withdrawals are much less. Though more irrigation systems are added each year, the influence of rainfall during the irrigation season is the primary factor in determining the amount of irrigation that takes place.

The estimated monthly irrigation pumpage is displayed graphically in Figure 27 along with average monthly network precipitation. These pumpage values show a tendency for lower irrigation amounts during times of greater precipitation and vice versa, but also show that irrigation is dependent on the timing of precipitation. For example, only 30 bg were pumped in 2000 (Y ear Eight), even though Y ear Eight show ed a deficit of 9.5 inches (Table 6). This was because significant precipitation fell during the summer of 2000, reducing the need for irrigation. Y ear 15 was only the ninth driest year of network operation, but rnaked second highest for irrigation pumpage because the summer months were so dry (i.e., M ay, J uly and A ugust received less than 67 percent of their respective average monthly precipitation). The influence of the reduced rainfall is evident in both the increased amount of water withdrawn for irrigation and in lower groundwater levels throughout the study area. Table 6 also shows that for 10 of the past 12 years, rainfall has been below the 30-year (1971-2000), historical average of 36.76 inches (average of Havana and $M$ ason City), although the timing of rainfall during the growing season has the most impact on the amount of irrigation withdrawals.

Figure 27. Estimated irrigation pumpage and average monthly precipitation, Imperial V alley

## Summary

For Y ear Fifteen of the rain gauge network operation (September 2006-A ugust 2007), the netw ork received an average of 31.94 inches of precipitation, 1.90 inches less than the network 14 -year average precipitation of 33.84 inches. For the year as a whole, precipitation was near average, although below average precipitation fell during the spring and summer seasons. Traditionally, groundwater levels tend to peak in most wells in the Imperial V alley during the spring and early summer, then decline in late summer and autumn when groundwater is evaporated and transpired back into the atmosphere by growing crops, and as a result of seasonal irrigation withdrawals. In Y ear Twelve, 2003-2004, some wells declined throughout the entire year, until showing a slight recovery in M ay 2004. For those wells, the highest water levels for the year were in September 2003. Therefore, the wetter-than-average autumn of 2004 brought about a marked increase in groundwater levels as the aquifer recovered from the previous dry weather. A s a result of four relatively dry years, $Y$ ear Eleven-Y ear F ourteen, groundwater levels have been decreasing since $Y$ ear Twelve. Since February 2005, as rainfall again fell significantly below average, groundwater levels declined in most wells to the lowest levels recorded during the study. The Snicarte well, for example, went dry and prompted the decision to replace it with a deeper well nearby. Observations in 2007 have indicated limited recovery of water levels; but at their highest, these are still well below pre-2004 levels over most of the study area.

With the data gathered at the irrigation test site, a better understanding of the relationship among precipitation, pumpage, stream flow in Crane Creek, and groundwater levels has been developed. For the five years of observations at this site, we found that groundwater levels remained above the level of Crane Creek, even during periods of irrigation, which indicates that the system was discharging to the stream even during the summer under irrigation conditions. W ater levels on both sides of Crane Creek was lower when the irrigation system is operating, which reduces groundwater discharge to the stream. However, water levels are not lower than the stream, so there was no reversal of flow from the stream. This data is being used as input to a computer flow model.

Ten pressure transducers installed at study wells have shown mixed results but indicate that the amount of rainfall, depth to water, and distance to a nearby stream all influence how quickly and to what extent groundwater levels rise in the aquifer after a precipitation event. The Easton well provides evidence that recharge is occurring over a fairly short time period (several days or less after a significant precipitation event). We expect to have more supporting data to analyze as more storm events of greater magnitude occur in the future.

Y ear Fifteen included the second highest irrigation withdrawal, even though it was only the ninth driest year of the study. This highlights the importance of rainfall timing on irrigation use.

Appendix A. Hydrographs, Imperial Valley Observation Well Network

## Appendix A. Hydrographs, Imperial Valley Observation Well Network

This appendix shows hydrographs of groundwater levels in each of the Imperial V alley observation wells. The hydrographs also include monthly precipitation totals from the nearest rain gauge or average of nearby gauges from the Imperial V alley rain gauge netw ork, and Illinois River stage for wells near the river. The hydrographs maintain a common y-axis range ( 25 feet).

Note: Bold numbers are the shallowest groundwater levels for the calendar year; italic numbers are the deepest groundwater levels. Shaded areas distinguish between years.

## Appendix C. Site Descriptions, Imperial Valley Rain Gauge Network

## Appendix C. Site Descriptions, Imperial Valley Rain Gauge Network

This appendix contains site descriptions of each rain gauge site in the IVWA network as of August 31, 2007. Sites that have been relocated since the network was established in August 1992 are so noted in the "Placement" portion of their site description. Sites with shaded descriptions have been removed from the network.

| SITE DESCRIPTION |  |  |
| :---: | :---: | :---: |
| Site Number: 1 |  |  |
| County: Tazewell | Latitude: $40^{\circ} 28^{\prime} 3^{\prime \prime}$ | Longitude: $89^{\circ} 50^{\prime} 9$ " |
| Property Owner: Melvin Fornoff |  |  |
| Address: 10200 Fornoff Road, Manito, IL 61546 |  |  |
| Telephone: 309-968-6653 |  |  |
| Permission Date: 8-10-92 |  |  |
| Installation Date: 8-25-92 |  |  |
| Gauge Mfrs. No.: 4695 | Gauge ID No.: SWS 5068 |  |
| Placement: Near apple/pear trees, northeast of a garage. Property on east side of 450 E. in Tazewell County, north of 1000 N. Large dog. Gauge 15 meters northwest of lat/long reading. Station removed from the network in September 1995. |  |  |

| SITE DESCRIPTION |  |  |
| :--- | :--- | :--- |
| Site Number: 2 |  |  |
| County: Tazewell | Latitude: $40^{\circ} 28^{\prime} 42^{\prime \prime}$ | Longitude: $89^{\circ} 45^{\prime} 54^{\prime \prime}$ |
| Property Owner: Ken Becker |  |  |
| Address: 8479 Townline Road, Manito, IL 61546 |  |  |
| Telephone: 309-545-2207 | Gauge ID No.: SWS 5030 |  |
| Permission Date: 8-15-92 |  |  |
| Installation Date: 8-25-92 | Gauge Mfrs. No.: 4723 |  |
| Placement: Moved 30 ft to northeast in same yard on 8-13-07, about 15 ft east of a yard shed. <br> In back yard (grass) near garbage burner. Property on south side of 1100 N. in Tazewell <br> County, west of 900 E. Gauge 2 meters west of lat/long reading. |  |  |

## Appendix C. (continued)

| SITE DESCRIPTION |  |  |
| :--- | :--- | :--- |
| Site Number: 3 |  |  |
| County: Tazewell | Latitude: $40^{\circ} 28^{\prime} 56^{\prime \prime}$ | Longitude: $89^{\circ} 37^{\prime} 33 "$ |
| Property Owner: Lonn Schleder |  |  |
| Address: 11177 S. 14th Street, Pekin, IL 61554 |  |  |
| Telephone: 309-348-2447 |  |  |
| Permission Date: 8-10-92 |  |  |
| Installation Date: 8-25-92 | Gauge ID No.: SWS 3693 |  |
| Gauge Mfrs. No.: 1463 |  |  |
| Placement: Moved 5-13-94 to a position about 60 meters north-northeast of original position, <br> which was in a back pasture along a wire fence between a white aluminum shed and a large <br> tree. Present position is between a garage and another shed near a well. Property on northwest <br> corner of the intersection of 1600 E. and 1100 N. Gauge 50 meters north-northwest of lat/long <br> reading. |  |  |

| SITE DESCRIPTION |  |  |
| :--- | :--- | :--- |
| Site Number: 4 |  |  |
| County: Mason | Latitude: $40^{\circ} 24^{\prime} 29 "$ | Longitude: $89^{\circ} 54^{\prime} 41^{\prime \prime}$ |
| Property Owner: Ellis Popcorn (Maureen Hanks) |  |  |
| Address: 24095 County Road 2330 E., Topeka, IL 61567 |  |  |
| Telephone: 309-535-3840 |  |  |
| Permission Date: 8-10-92 | Gauge ID No.: SWS 6573 |  |
| Installation Date: 8-25-92 |  |  |
| Gauge Mfrs. No.: 7382 | Placement: South of large white office building, between two trees in a grassy area. Property <br> on east side of 2340 E. in Mason County, northeast of Goofy Ridge. Gauge 10 meters south- <br> southwest of lat/long reading. |  |

## Appendix C. (continued)

| SITE DESCRIPTION |  |  |
| :---: | :---: | :---: |
| Site Number: 5 |  |  |
| County: M ason | L atitude: $40^{\circ} 24^{\prime}$ 29" | Longitude: $89^{\circ} 50^{\prime} 19{ }^{\prime \prime}$ |
| Property Owner: J oseph M eyer |  |  |
| Address: 24234 County Road 2750 E., Topeka, IL 61567 |  |  |
| Telephone: 309-968-6378 |  |  |
| Permission Date: 8-10-92 |  |  |
| Installation Date: 8-25-92 |  |  |
| Gauge M frs. N 0.: 5985 | Gauge ID No.: CDA 000130 |  |
| Placement: N ext to stone drive in a pasture in front of house. Property on west side of 275 E. in M ason County, south of 2500 N. Gauge 3 meters east of lat/long reading. Station removed from network in September 1995. |  |  |

| SITE DESCRIPTION |  |  |
| :---: | :---: | :---: |
| Site Number: 6 |  |  |
| County: M ason | L atitude: $40^{\circ} 22^{\prime \prime} 42$ | Longitude: $89{ }^{\circ} 43^{\prime} 16^{\prime \prime}$ |
| Property Owner: Lawrence Whiteford |  |  |
| Address: 22172 N. County Road 3400 E., M anito, IL 61546-7988 |  |  |
| Telephone: 309-968-6234 |  |  |
| Permission Date: 3-22-01 |  |  |
| Installation Date: 3-22-01 |  |  |
| Gauge Mfrs. No.: 5295 | Gauge ID No.: SWS |  |
| Placement: Gauge was moved on 3-22-01 approximately 1.9 miles south-southeast of old location, or about 0.4 miles north of 2180 N . on 3400 E ., Mason County. New location is in an open area west of machine shed. Old location was on west side of 3300 E . in M ason County, just south of $2400 \mathrm{~N} ., 18$ meters south of lat/long reading. |  |  |

## Appendix C. (continued)

| SITE DESCRIPTION |  |  |
| :---: | :---: | :---: |
| Site Number: 7 |  |  |
| County: Tazewell | Latitude: $40^{\circ} 24^{\prime} 24^{\prime \prime}$ | Longitude: $89^{\circ} 37^{\prime} 29^{\prime \prime}$ |
| Property Owner: David V an Orman |  |  |
| Address: 5801 W arner Road, Green V alley, IL 61534 |  |  |
| Telephone: 309-352-5673 |  |  |
| Permission Date: 8-10-92 |  |  |
| Installation Date: 8-25-92 |  |  |
| Gauge M frs. No.: 5935 | Gauge ID No.: -- |  |
| Placement: M oved in M ay 1993 to a position south of a barn with a green roof, near edge of field. Original position was 30 meters to the northeast, north of the same barn. B oth positions in Tazewell County, just west of 1600 E. Gauge 17 meters west-northwest of lat/long reading. |  |  |

| SITE DESCRIPTION |  |  |
| :---: | :---: | :---: |
| Site Number: 8 |  |  |
| County: M ason | Latitude: $40^{\circ} 20^{\prime} 56^{\prime \prime}$ | Longitude: $90^{\circ} 1^{\prime} 18{ }^{\prime \prime}$ |
| Property O wner: c/o Steve Havera, Forbes Biological Station |  |  |
| Address: P.O. Box 49, Havana, IL 62644 |  |  |
| Telephone: 309-543-3950 |  |  |
| Permission Date: 6-3-02 |  |  |
| Installation Date: 6-3-02 |  |  |
| Gauge M frs. No.: 2000 | Gauge ID No.: US14 |  |
| Placement: New location as of $6-3-02$, Illinois N atural History Survey station on Quiver Creek, 0.2 mile northeast of old location. From 4-20-00 to 6-3-02, was on Blakely property located on north side of 1950 N . in M ason County west of $1900 \mathrm{E} ., 0.5$ mile northwest of old site east-southeast of house near a small tree. |  |  |

| Installation Date: 8-26-92 |  |  |
| Gauge M frs. No.: 4718 | Gauge ID No.: SWS 5081 |  |
| Placement: A long a wire fence separating home property from pigpen, northwest of house. Property located on west side of Route 97 on southern end of a large curve between 900 N and 800 N . Gauge 14 meters northwest of lat//ong reading. |  |  |

| SITE DESCRIPTION |  |  |
| :---: | :---: | :---: |
| Site N umber: 20 |  |  |
| County: M ason | Latitude: $40^{\circ} 11^{\prime} 46^{\prime \prime}$ | Longitude: $89{ }^{\circ} 54^{\prime} 56{ }^{\prime \prime}$ |
| Property Owner: Wanda K rause |  |  |
| Address: R.R. \#1, Box 109, Easton, IL 62633 |  |  |
| Telephone: 309-562-7528 |  |  |
| Permission Date: 8-11-92 |  |  |
| Installation Date: 8-26-92 |  |  |
| Gauge M frs. No.: 3371 | Gauge ID No.: US 14 |  |
| Placement: In yard of Jon K rause just north of east-west lane and west of lane to the $K$ rause home. The gauge was moved to this position in early 1995. The previous location on the east side of 2400 E . in M ason County near J on K rause mail box was in a strawberry patch al ong the same lane about 250 meters to the west on the W anda K rause property. Gauge 150 meters east of lat/long reading. |  |  |

| Permission Date: 8-11-92 |  |  |
| Installation Date: 8-26-92 |  |  |
| Gauge M frs. No.: 5947 | Gauge ID No.: -- |  |
| Placement: Next to two tanks and a sign in a small grassy area surrounded by truck access. Property located at A dkins Farms on south side of 300 N . (east of Route 78) in M ason County. Gauge 2 meters south of lat/long reading. Station removed from netw ork in September 1995. |  |  |

Appendix D. Instructions for Rain Gauge Technicians

# Appendix D. Instructions for Rain Gauge Technicians 

## A. Use Central Standard Time Year-Around

From November through M arch, Illinois is in the Central Standard Time zone, so your watch will indicate the correct time and date to be noted on the chart. From A pril through October when Illinois is in the Central Daylight Time zone, subtract one hour from your watch reading.

## B. Order of Servicing

## 1) Old Chart

a) U nlock and open (slide up) door on the side of the instrument case and then lock door in place to prevent it from falling.
b) Depress the bucket platform casting to mark the OFF time position on the chart (a vertical trace will be written by the pen).
c) Note the time on your watch, and move the pen point and arm away from the chart by pushing out on the pen shifter.
d) Lift up on the chart cylinder that contains the chart to disengage it from the chart drive, and remove it.
e) Remove the chart from the cylinder and write the OFF date and time on the chart on the red line at the right end of the chart.

## 2) Bucket

a) Remove the collector from the top of the gauge by rotating it clockwise to disengage the tongue-and-groove assembly.
b) Carefully lift the bucket off the weighing platform. If there is water in it and no antifreeze, dump the water on the ground.
c) Reposition the empty bucket on the platform.
d) Reinstall the collector by setting it on top of the rain gauge case and turning it counterclockwise until the tongue-and-groove assembly meshes.
e) During wintertime operation, when 2 inches (about one quart) of antifreeze is in the bucket to prevent freezing, leave the liquid in the bucket until the chart reading passes the 6 -inch mark. At that point, pour the bucket contents into a sealed container and dispose of properly. DO NOT POUR SOLUTION ONTO THE GROUND! If wintertime conditions prevail, recharge the empty bucket with 2 inches of antifreeze. Reposition the dry bucket on the platform and reinstall the collector assembly.
f) In the winter, stir the contents of the bucket to keep the antifreeze mixed with the water.
g) At any time of the year, once the collector is repositioned, check the gauge to make sure the collector orifice top edge is level.

## 3) New Chart

a) Copy the OFF time from the old chart to the ON time on the new chart (another red line on the end of the chart), and write your site number on the chart.
b) Clip the new chart to the cylinder, making sure the crease at the right end of the chart is sharp and the chart is tight on the cylinder.
c) Reinstall the chart cylinder onto the chart drive, making sure the chart cylinder and drive gears mesh. Simply push down on the cylinder and wiggle it a little. Y ou should feel some resistance if done correctly.
d) $\quad$ M ove the pen arm and point over to the chart cylinder with the pen bracket and rotate the cylinder counterclockwise until the pen point coincides with the correct ON time position.
e) L et the pen point rest right on the chart and depress the platform casting again to make a small, vertical line denoting the ON time position. This al so ensures that the pen point is writing correctly. If it is not, check the tip of the pen point to see why it is not drawing. Replace if necessary. It helps if the word "ON" is written on the chart near the ON line for later chart editing. Rezero the pen point if necessary by turning the fine adjustment screw. It is a good idea to "zero" the pen near the 0.25inch mark to prevent evaporation from taking the pen point below the zero line.
f) When you are sure that everything is in order, carefully unlock the door, push the door down, and lock it in place for another month.

## 4) Data Logger

a) Plug HP200X Palmtop PC into the data logger and download data.
b) Transfer data to flash card.
c) $\quad \mathrm{M}$ ail flash card and charts to ISW S.

## 5) Problems

a) If you notice anything unusual about the gauge or the chart drive, write a note on the upper right corner of the old chart.
b) If you think the problem requires immediate attention, call $N$ ancy W estcott collect at 866-292-7305 or e-mail her at nan@illinois.edu to relay the information. Situations worthy of immediate attention include questions concerning the operation described above, premature chart-drive stoppage, data logger problems, or unauthorized tampering with the gauge. Immediate repairs will be scheduled if necessary.
c) W rite a note describing problems and send with the charts when mailing charts to the ISWS.
d) Also, write a note or call when new supplies are needed: antifreeze, pen tips, batteries, charts, spare clock drive, envelopes, and stamps.

## 6) Annual Tasks

a) In the fall, usually N ovember, the gauges are winterized. The evaporation shield is removed. A ntifreeze is added to the bucket. The clock batteries are changed.
b) U sually in December, the batteries in the data loggers are changed by the ISW S field technician.
c) U sually in M arch or A pril, the antifreeze is removed as per 2e, and the evaporation shield is reinstalled.
d) Over the span of two years, all gauges should be recalibrated and cleaned in the field by the ISW S field technician.
e) A ny gauge thought to be problematic (too high or too low) will be tested against the official ISW S 8-inch non-recording gauge at the ISW S.

## C. Change in Site Status

If the gauge is no longer wanted on the property, please contact $N$ ancy W estcott. Either call her toll-free at 866-292-7305 or e-mail her at nan@ illinois.edu immediately so that new arrangements can be made. It is important to try to keep the sites near the same locations during the course of this project because precipitation generally can vary greatly over short distances.

Appendix E. Documentation, Imperial Valley Rain Gauge Network Maintenance, 2006-2007

## Appendix E. Documentation, Imperial Valley Rain Gauge Network Maintenance, 2006-2007

This appendix documents major maintenance work carried out at sites in the Imperial V alley rain gauge netw ork from September 1, 2006 through A ugust 31, 2007.

1. Winterized, including changing clock batteries, removing evaporation shield, and adding antifreeze to all gauges on N ovember 3-4, 2006.
2. Replaced gauge at site 2 on February 22, 2007.
3. Replaced cylindrical shelter for the gauge at site 10 on M ay $15,2007$.
4. M oved gauge at site 2 on A ugust 13, 2007. The gauge was moved about 30 feet to the northeast to a point close to an unpaved drive on the east and a small yard shed $\sim 15$ feet to the west, out of the way of the sprinkler system.

Appendix F. Hydrographs, Transducer Data at the Test Site

## Appendix F. Hydrographs, Transducer Data at the Test Site

This appendix shows hydrographs of groundwater levels in each of the wells in place at the test site. The data are not continuous on each hydrograph due to removal of the transducers at various wells at various intervals.

Note:
The tables are based on the total number of precipitation events in a given month, season, or year.

Appendix I. Documentation of Precipitation Events in the Imperial Valley, 2006-2007

## Appendix I. Documentation of Precipitation Events in the Imperial Valley, 2006-2007

This appendix documents all storm event amounts, start times, and durations, and notes those that exceed an expected event amount (for 1-year to 100-year recurrence intervals, Tablel-1) during the period September 1, 2005-A ugust 31, 2006 (Table I-2). Table I-3 documents the storm event amounts for each gauge. The maximum storm amount in a given network storm period is used to compute the recurrence interval for a given precipitation event. The same information for previous years is found in Scott et al. (2002), W ehrmann et al. (2004, 2005), and Wilson et al. (2008 a, b). Individual network storm durations of one hour to ten days were considered. The precipitation amounts and storm durations for 1- to 100-year recurrence intervals for west-central Illinois are given in Table I-1 (Huff and A ngel, 1989).

To determine the return frequency of any storm in Table l-2 or l-3, obtain the storm duration from the tables, then look in the left-hand column of Table I-1 to locate the storm duration that equals or just exceeds the storm duration in Table I-2 or I-3. If the precipitation for the event at any gauge in Tablel-2 or l-3 exceeds the amount in Table I-1, obtain the return frequency by looking at the heading of the right-hand column that the precipitation amount exceeds. For example, Table I-3 indicates storm number 1754 has a duration of 14 hours. This storm duration falls between the 12and 18 -hour storm duration in TableI-1. A ssume an 18 -hour storm duration. Table I-3 indicates the gauge at site 11 recorded precipitation equal to 4.21 inches. Therefore, site 11 exceeded the 10-year return frequency amount (4.09 inches) for an 18-hour storm.

Tablel-3 indicates whether the maximum precipitation for the storm exceeds the expected amount for the observed storm duration (1-year to 100-year recurrence intervals) considered. A storm recurrence frequency of 50 years means that a storm of this intensity and duration would be expected once every 50 years.
